The strand bias of the minor allele reads in HM pairs (depth ≥ 10) belongs to the locus

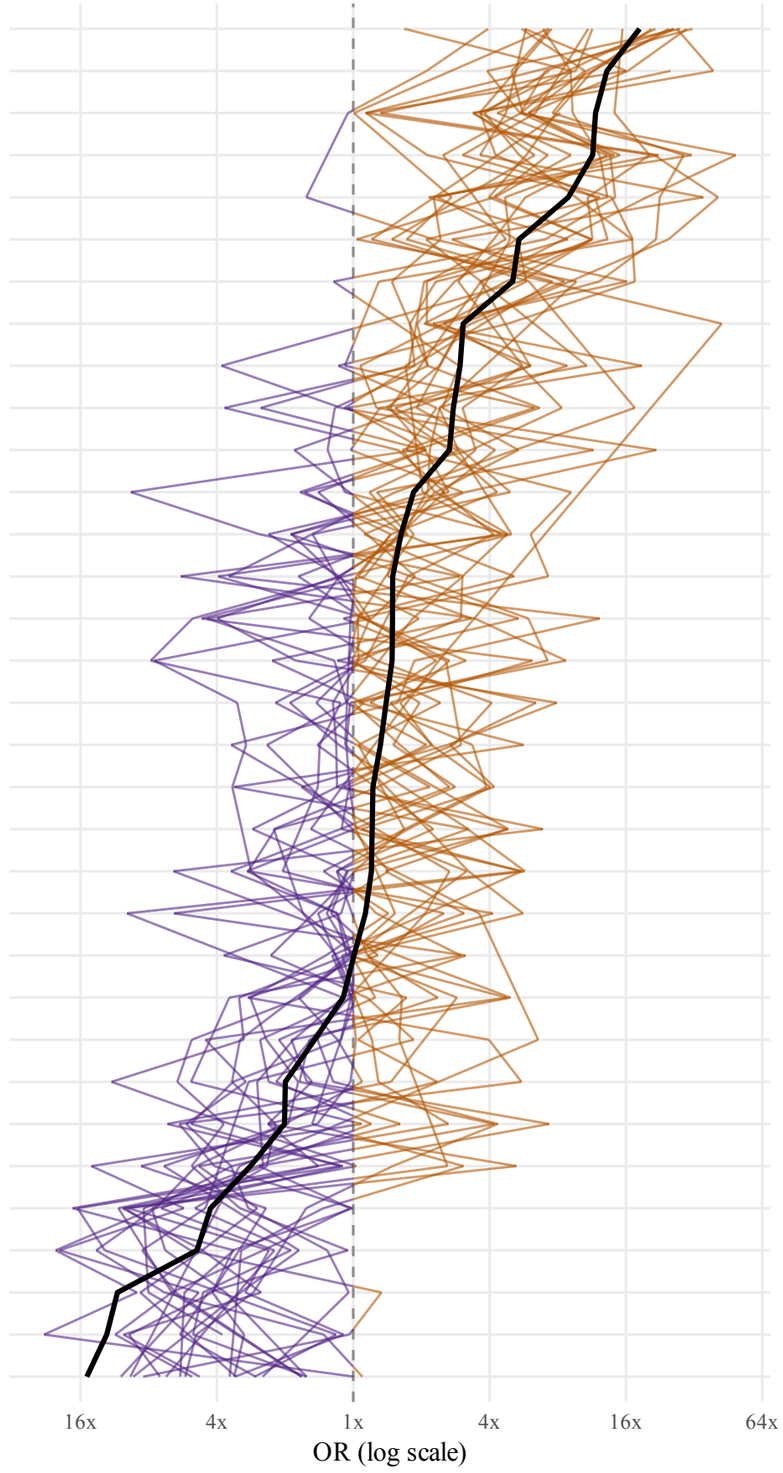

A Minor allele rate on reverse and forward reads

Small points represent the % of minor allele reads on the FWD (red) and RV (blue) strand of one sample,
large points all HM reads pooled per locus. Right: Mantel-Haenszel odds ratio (95% CI) of minor allele reads on FWD vs RV;
coloured = strand bias significant after Bonferroni (CMH p < 0.05/33: 17 of 33 loci), grey = not significant.

B Minor allele strand odds ratio per sample

One line per sample (OR with +0.5 Haldane correction;
red = more on FWD, blue = more on RV), black line = Mantel-Haenszel OR of all samples.
Woolf test: samples differ at 0 of 33 loci (smallest p = 0.14).

CMH: strand bias significant at 17 of 33 loci after Bonferroni. Woolf: samples differ at 0 of 33 loci.
GLMM (reads not independent): strand-bias SD between loci 1.37 (p = 1e-135) vs between samples 0.00 (p = 0.5).
